Hospital: **Goustave Roussey International Egypt**

MULTISCLICE POST CONTRAST C.T. EXAMINATION OF THE CHEST, ABDOMEN AND PELVIS REVEALED:

Cmpared to last study dated 5-1-2025 current study reveals;

I- CHEST:

- stationary course as regard the previously noted Left mild to moderate pleural effusion with underlying left lower lobar consolidation collapse.
- Right lower lobar thick atelectatic bands with related bronchectatic changes
- No hilar or mediastinal masses or lymph node enlargement.
- No pleural or pericardial collection.
- Normal plain CT appearance of the heart and great vessels.

II- ABDOMEN AND PELVIS:

- Average sized liver showing homogenous parenchymal attenuation. No dilated biliary radicles.
- Marked regression of the size and number of the previously noted few hepatic focal lesions, the largest still seen in the right lobe segment VIII measuring 8 mm (compared to 12 mm in the previous study), two of the lesions are hardly seen in today's study
- Both kidneys are normal site, average sized and showing smooth regular cortical outline and preserved parenchymal thickness and function. No stones or back pressure changes.
- Normal C.T appearance of the spleen, pancreas, suprarenal glands, aorta and IVC.
- The urinary bladder shows no evidence of gross masses or diverticulae or stones.
- Normal appearance of the pelvic organs with no pelvic masses or collections.
- No abdominal or pelvic lymphadenopathy.
- No ascites.

III- Bony skeleton:

Stionary coure as regard the Multiple sclerotic lesions with diffuse heterogenous density of left femoral head , bilateral iliac, sacral body, most lumbar and dorsal vertebral bodies, sternum, as well as ribs

Opinion

- **Regressive course regarding the size and number of the previously noted hepatic focal lesions.**
- **Stationary course regarding the rest of the study.**

Detailed Medical Report

السيد	

تحية طيبة وبعد,,

إيماء للطلب المقدم من		**بشأن تقرير طبي للمريض**	
بقسم:		**رقم طبي:**	

ننشرف بأن نوضح فيما يلي تقريرا عن حالته

تاريخ وساعة الدخول :		**تاريخ وساعة الخروج :**	

وبعد الكشف والفحوصات والمتابعة وجد انه

The patient is a 60-year-old individual, postmenopausal, with a history of left breast cancer treated with breast-conserving surgery in 2018 followed by adjuvant aromatase inhibitor therapy. The disease has progressed to metastatic breast cancer involving bone, pleura, and liver, with prior systemic regimens including Faslodex, Ibrance (8 cycles), docetaxel, radiotherapy to the hip, humeral fracture, and subsequent cycles of capecitabine and carboplatin-gemcitabine (Gemzar) initiated in October 2025. Comorbidities are not listed.

The most recent biopsy of the metastatic disease demonstrated estrogen receptor 8/8, progesterone receptor 6/8, and HER2-negative status. Imaging performed on 25 April 2026 showed a bone scan with residual osseous lesions in the shoulder, sternum, both clavicles, dorsal vertebrae, and left knee. A CT scan on 16 April 2026 reported a reduction in size of a previously noted high-frequency lesion, the largest measuring 8 mm compared with 12 mm earlier. Subsequent CT on 19 July 2026 identified a minimal left pleural effusion and several high-frequency lesions in both lung lobes, the largest 10 mm, along with stable osseous disease. The patient continues on gemcitabine-carboplatin, now completing 13 cycles, and has recently developed multiple new skin nodules over the presternal area, neck, and both breasts.

The referring team recommended baseline CT of the chest, abdomen, and pelvis with tumor markers, and a biopsy of the skin nodules for ER, PR, and HER2 assessment. The multidisciplinary team agreed to initiate aromatase inhibitor therapy with aromazone plus everolimus (Afinitor) and to reassess the patient after four months with repeat CT imaging and tumor marker evaluation.

Patient Name : مريم السيد على
Analysis ID : 385011
Age : 53 Y
Gender : Female
Referred By Prof. Dr. : محمد فلان
Clinical Diagnosis : Left breast mass
Nature of Specimen : Wide local excision & axillary clearance
Receiving Date : 10/06/2019
Patient ID : 307584

PATHOLOGY REPORT

Gross :

Two specimens were received designated as:
1- Wide local excision specimen measures 8x7x4.5 cm. Cut section revealed firm gritty tumour tissue with ill defined borders, measured 3.6x3.5x2.8 cm, 0.5 cm away from the nearest margin. A separate nodule measured 1x1 cm was received along.
2- An axillary fibrofatty tissue measuring 12x9x2 cm. Dissection revealed 18 lymph nodes, the largest 3x1.6 cm, with grayish cut section.

Microscopic :

Sections examined from specimen (1) received revealed breast tissue showing infiltrating tumour tissue formed of irregular groups of malignant ductal cells showing moderate nuclear pleomorphism and hyperchromasia. There is moderate attempt at tubular formation. There is moderate number of mitotic figures. There are few tumour embol. No tumoural necrosis. There is marked desmoplasia. No intraductal component
The surrounding breast tissue showed acanosis.
Surgical margins are free.
Sections examined from the axillary nodes revealed metastatic deposits in 1 out of 18 nodes with no capsular infiltration.

Diagnosis :

Left breast mass, Wide local excision & axillary clearance, INFILTRATING DUCT CARCINOMA GRADE II, NO INTRADUCTAL COMPONENT, FREE SURGICAL MARGINS, AXILLARY LYMPH NODE METASTASIS, L.N. 1 / 18, WITH NO CAPSULAR INFILTRATION (N1).
TUMOR STAGE: pT2 pN1

MULTISCLICE POST CONTRAST C.T. EXAMINATION OF THE CHEST, ABDOMEN AND PELVIS REVEALED:

I- CHEST:

- Left moderate pleural effusion with underlying left lower lobar consolidation collapse.
- Right lower lobar consolidation with surrounding area of linear fibrotic bands
- No consolidation or collapse.
- No hilar or mediastinal masses or lymph node enlargement.
- No pleural or pericardial collection.
- Normal plain CT appearance of the heart and great vessels.

II- ABDOMEN AND PELVIS:

- Average sized liver showing homogenous parenchymal attenuation. No dilated biliary radicles. Multiple hypodense focal lesions seen in both lobes, the largest measures 12 mm, all showed marginal enhancement
- Both kidneys are normal site, average sized and showing smooth regular cortical outline and preserved parenchymal thickness and function. No stones or back pressure changes.
- Normal C.T appearance of the spleen, pancreas, suprarenal glands, aorta and IVC.
- The urinary bladder shows no evidence of gross masses or diverticulae or stones.
- Normal appearance of the pelvic organs with no pelvic masses or collections.
- No abdominal or pelvic lymphadenopathy.
- No ascites.

III- Bony skeleton:

Multiple sclerotic lesions with diffuse heterogenous density of bilateral iliac, sacral body, lumbar and dorsal vertebral bodies, sternum, as well as ribs

Opinion:

- Known case of breast cancer.
- Moderate left pleural effusion with underlying left lower lobar consolidation collapse.

FOLLOW UP MR EXAMINATION OF THE BRAIN

Technique:

Axial T1, T2 ,FLAIR, diffusion & ADC WIs
Coronal T2WIs
Sagittal T1WIs

Findings:

- **Compared to the previous report done on 30/01/2025, the current study showed no interval changes**
- A stationary focus that noted in the left superior frontal periventricular cerebral white matter. It elicits high signal intensity in T1, T2 and FLAIR images. It is not surrounded by edema and exert no mass effect with no diffusion restriction.
- Mildly dilated cortical sulci, sylvian fissures and extra-axial CSF spaces as well as the cerebral ventricular system.
- No other areas of abnormal signal intensity.
- No evidences of mass lesions or abnormal enhancement seen.
- No intra-or extra-axial areas of blood intensity.
- Normal cerebellum, brain stem & cervico – medullary junction.
- Normal sellar region.
- No intracerebral or extra axial hematomas

OPINION:

Stationary course regarding a small left frontal periventricular focus of non-specific altered signal intensity, likely ischemic changes.
Age matched involutional brain changes.

Best regards
Dr. Jaber Gliwan
Dr Mahmoud Abdelmohsen.FEBR.FABR

Tc 99m MDP whole body bone scan

Technique:

- Whole body images were acquired 180 minutes following IV injection of 20 mCi of the tracer.

Findings:

- Multiple focal and diffuse spots of active tracer uptake are seen in skull bones, mandible, both shoulders, right humerus, sternum, both scapulae, both clavicles, multiple bilateral ribs, multiple levels at most of dorsal and lumbar spine, sacrum, both sacroiliacs, both iliac bones, both acetabulae, both ischial bones, both femora, around left knee joint.

Opinion:

- ***Widespread metastatic osseous deposits, for follow up bone scan.***

Truly yours

Non-Contrast MSCT scan examination of the Chest, Abdomen and Pelvis, revealed:

Clinical Background: Known case of breast cancer

No previous imaging studies available, limited comparison made to the submitted report dated19/07/2026:

I) Chest:

- Applied right CVC with the distal tip projecting over the cavo-atrial junction.
- Diffuse prominent interlobular septal and fissural thickening of the left lung.
- The anterior left lung and lingula show peripheral subpleural reticulations, likely post radiotherapy changes.
- Associated left sided volume loss and mild elevation of the left hemi-diaphragm.
- RUL anterior segment 4mm nodule is noted, indeterminate.
- Right lower apical thick fibrotic bands with mild bronchiectatic and subsegmental atelectatic changes.
- Still noted left minimal to mild pleural effusion with underlying left basal thick pleuro-parenchymal thick scarring and subsegmental atelectatic changes.
- No right pleural collection.
- No newly developed consolidation, cavitations or masses.
- No pathologically enlarged mediastinal lymph nodes.
- No gross cardiomegaly. No pericardial effusion.
- Bilateral elastofibroma dorsi, more sizable on the right side.
- Left breast parenchyma shows few calcific foci.

[[DOCTYPE:CT_SCAN]]
CT Scan

Name: **Mrs. Maryam El-Sayed Ali Ahmed**

II) Abdomen and Pelvis:

- Average size of the liver with homogenous parenchymal attenuation. Few inconspicuous focal lesions are identified.
- Normal non-contrast CT appearance of the spleen, pancreas and both kidneys.
- Atheromatous calcifications of the aorta.
- No gross abdominal or pelvic lymph node enlargement.
- IUD is seen in utero, no gross uterine or adnexal mass lesions.
- No abdominal ascites or pelvic collections.
- Normal appearance of the urinary bladder.
- Marked asymmetric atrophy of the right sided pelvic musculature.
- The scanned bony cage and vertebrae show multiple heterogenous osseous texture with metastatic deposits, predominantly sclerotic in appearance.

Conclusion:

- **Diffuse prominent interlobular septal and fissural thickening involving the left lung, raising the possibility of lymphatic tumor involvement.**
- **Superimposed post radiotherapy fibrotic changes in the anterior lung/lingula with associated left sided volume loss.**
- **Left minimal pleural effusion.**
- **Few inconspicuous hepatic focal lesions, for contrast enhancment assessment.**
- **For correlation with previous unavailable prior imaging studies.**

Truly yours;
Dr. Enas Samy, MD

MRI EXAMINATION OF THE BRAIN

MR Technique:

- Axial T1, T2 and FLAIR WI's
- Sagittal T1WI
- Coronal T2 WI
- Axial,sagittal and coronal T1WIs with contrast.
- DWI & ADC sequence.

MR findings:

- Widened cortical sulci, basal cisterns, cerebellar folia and extra-axial CSF spaces with prominence of the ventricular systems.
- Two tiny non-enhancing foci of altered signals are seen in the right frontal lobe and displaying high signals on both T2WIs and FLAIR sequences ,isointensity of T1WIs with no evidences of restricted diffusion seen herein.
- No other cerebral, cerebellar or brain stem areas of altered MR signal/abnormal enhancement/foci of restricted diffusion.
- No midline shift or deformity.
- No extra axial collections or masses.
- No cerebello pontine angle masses.
- No gross posterior fossa abnormalities.
- Cuts taken in the para-sellar regions are unremarkable.
- Flattened the pituitary gland towards the flood of the dorsum sellae,measuring about 2.9mm in its height and the rest of dorsum sellae is replaced with CSF-signal.
- Cuts taken in the orbits are unremarkable.
- **Cuts taken in the para-nasal sinuses revealed mild ethmoidal and left sphenoidal sinusitis with a tiny polyp seen in the left maxillary antrum and measures about 8.2x5.9mm in dimensions.**
- **Cuts taken in the mastoid air cells revealed bilateral mastoiditis.**
- Intact cervico medullary junction.

- **Brain involutional changes.**
- **Two lacunar infarcts in the right frontal lobe.**
- **Flattened the pituitary gland towards the floor of the dorsum sella, and is rest of the dorsum sellae is replaced with CSF-signal,denoting a partial empty sella syndrome.**
- **Otherwise,normal study.**

Prof/Hanan El-Ahwal.
